Check for outliers

```
In [14]: par(mfrow=c(1,5), mar=c(2,2,2,2))
boxplot(df$Item_Weight,main='Item Weight')
boxplot(df$Item_Visibility,main='Item Visibility')
boxplot(df$Item_MRP,main='Item MRP')
boxplot(df$Outlet_Establishment_Year,main='Outlet Establishment')
boxplot(df$Item_Outlet_Sales,main='Outlet Sales')
```

```
In [15]: par(mfrow=c(2,3), mar=c(2,2,2,2))
    hist(df$Item_Weight,main='Item Weight',breaks=20)
    hist(df$Item_Visibility,main='Item Visibility',breaks=20)
    hist(df$Item_MRP,main='Item MRP',breaks=20)
    hist(df$Outlet_Establishment_Year,main='Outlet Establishment',breaks=20)
    hist(df$Item_Outlet_Sales,main='Outlet Sales',breaks=20)
```

The two variables with extreme values are item visibility and outlet sales. However, the extreme values are numerous and are consistent with the skewed distributions observed in the histogram. Therefore they are not considered outliers.

Next, check for correlations.

```

Linear Regression

8523 samples
    113 predictor

No pre-processing
Resampling: Cross-Validated (5 fold, repeated 3 times)
Summary of sample sizes: 6819, 6817, 6819, 6819, 6818, 6819, ...
Resampling results:

RMSE    Rsquared    MAE
    1077.878    0.6014958    759.3767</pre>
```

Tuning parameter 'intercept' was held constant at a value of TRUE

The RMSE is comparable to that of the model fit to the entire data set, indicating overfitting is minimal. Therefore the model will not be reduced further, nor will any regularization penalties be added.

Model Selection

The linear model is slightly better than the decision tree model in terms of cros validation RMSE, therefore the linear model will be selected as the final model.

The test data set is processed the same way as the training set.

```
In [89]: | test <- read.csv('C:/Datasets/SalesTest.txt',na.strings='')</pre>
          test$Item_Outlet_Sales <- 0</pre>
          test$ItemPrefix2 <- factor(substring(test[,1],1,2))</pre>
          test$ItemPrefix3 <- factor(substring(test[,1],1,3))</pre>
          test$ItemNumber <- as.numeric(substring(test[,1],4,5))</pre>
          itemID <- test[,1]</pre>
          test<-test[,-1]
          test$Item Fat Content <- factor(ifelse(test$Item Fat Content %in% c('reg','Regular')
          testX <- predict(dummyVars(Item_Outlet_Sales~.,df,fullRank=TRUE),test)</pre>
          dimnames(testX)[[2]] <- gsub(' ','',dimnames(testX)[[2]])</pre>
          processedtestX <- predict(preprocessparams, testX)</pre>
          processedtestX <- processedtestX[,-c(25,22,34)]</pre>
          IntertestX <- as.data.frame(processedtestX)</pre>
          for(a in 1:12){
               for(b in (a+1):13){
                   intername <- paste(sigfeaturelist[a], sigfeaturelist[b], sep='x')</pre>
                   IntertestX <- mutate(IntertestX,!!intername := processedtestX[,sigfeaturelis</pre>
               }
          }
          IntertestX <- as.matrix(IntertestX)</pre>
          fulltestX <- as.data.frame(processedtestX)</pre>
          for(a in siginterlist){
                   fulltestX <- mutate(fulltestX,!!a := IntertestX[,a])</pre>
          fulltestX <- as.matrix(fulltestX)</pre>
          finaltestX <- as.data.frame(fulltestX)</pre>
          for(a in continuouslist){
               cubname <- paste(a,'cub',sep='.')</pre>
               finaltestX <- mutate(finaltestX,!!cubname := fulltestX[,a]^3)</pre>
          finaltestX <- as.matrix(finaltestX)</pre>
          finaltestX <- finaltestX[,finalfeaturelist]</pre>
```

Then the model is used to predict sales for the test set.

```
In [90]: results <- predict(fulllinearmodel,finaltestX)

In [94]: resulttable <- as.data.frame(itemID)
    resulttable$Outlet_Identifier <- test$Outlet_Identifier
    resulttable$Item_Outlet_Sales <- results
    write.csv(resulttable,'C:/Datasets/SalesTestPredict.csv')</pre>
```
